

Customize your board device tree!

- ▶ Kernel developers write *Device Tree Sources (DTS)*, which become *Device Tree Blobs (DTB)* once compiled.
- ▶ There is one different Device Tree for each board/platform supported by the kernel, available in `arch/<arch>/boot/dts/<vendor>/<board>.dtb` (`arch/arm/boot/dts/<board>.dtb` on ARM 32 before Linux 6.5).
- ▶ As a board user, you may have legitimate needs to customize your board device tree:
 - To describe external devices attached to non-discoverable busses and configure them.
 - To configure pin muxing: choosing what SoC signals are made available on the board external connectors. See <http://linux.tanzilli.com/> for a web service doing this interactively.
 - To configure some system parameters: flash partitions, kernel command line (other ways exist)
